Rabies vaccine:	---	
Manufacturer:	---	
Vaccine lot #:	---	
Lot expiration:	---	

Notes
Heartworm Test: Negative Heartworm test results negative at this time. Owner advised on the importance of continued year-round heartworm prevention to protect against future infection. Monthly prevention recommended and discussed during visit. (L mandible has a small growth (pencil eraser size) with irregular surface but freely moveable/not-concerning. O says it is not problematic. Has intermittent areas of possible flea dirt @ tailhead but cannot find any fleas. Rec flea/tick prevention always.) *Making Quality Veterinary Care Accessible to Everyone* Please leave us a review on Google or Facebook to help us build our mission!

Hospital Visit Summary

Pet Name: Rosie

Owner Name: Rachel Washington

IF YOUR PET RECEIVED VACCINES TODAY

It is common for many pets to experience mild side effects following vaccination, similar to those that humans experience. Rarely does a pet need veterinary medical attention for these normal.

Some of the most common mild side effects seen after immunization include:

Redness, mild swelling, and tenderness at the vaccination site

Decreased activity levels (fatigue)

Loss of appetite

Low-grade fever

Nasal discharge, sneezing, coughing, or other respiratory symptoms, which may occur up to 2 to 4 days after an intranasal vaccine (vaccination with drops or sprays via the nostrils) is administered

If any of these signs lasts more than 24 hours or if your pet appears extremely uncomfortable, notify your veterinarian. If you fear your pet is having a reaction to a vaccine, please call us at **863-583-5060**.

It is also common for a pet to develop a small, firm nodule at the vaccination site. It should begin to shrink and vanish within 14 days. If the swelling lasts longer than 3 weeks or appears to get larger or more painful, contact your veterinarian.

Other less common but more serious side effects can occur within minutes to hours after vaccination. These reactions are considered to be medical emergencies, and you should seek veterinary care immediately if any of the following occur:

Collapse or fainting

Difficulty breathing

Persistent and severe coughing

Small, red, raised, itchy bumps over the body (hives)

Swollen or puffy eyes, muzzle, or face

Persistent vomiting or diarrhea

The vast majority pets are vaccinated without any problems each year. Closely monitor your pet, and report any problems to your veterinarian as soon as possible. Vaccines save countless lives and prevent devastating infectious diseases from threatening our pet loved ones. If you have any questions or concerns, please discuss them with your veterinarian.
